

**REPLACEMENT SPECIFICATION
WITH APPENDIX**

EXTERNAL REPAIR OF A COMPUTER

5

Field of the Invention

10 This invention relates to computers, computer repair and computer architecture. More particularly, the invention relates to a computer architecture and software that enables the computer to repair itself.

BENEFIT APPLICATIONS

15 This application is a continuation-in-part and claims the benefit of priority under 35 U.S.C. 119(e) and/or 35 U.S.C. 120 to:

 U.S. patent application Ser. No. 09/862,898, entitled, "A Computer with Switchable Components," filed May 21, 2001, naming Kenneth Largman and Anthony B. More and Jeffrey Blair as inventors, with Attorney Docket No.
20 A70543/RMA/LM, and commonly assigned to Self Repairing Computers, Inc., San Francisco, Calif.;

 U.S. Patent Application No. 10/075,136, entitled, "On-The-Fly Repair Of A Computer," filed Nov. 19, 2001, naming Kenneth Largman and Anthony B. More and Jeffrey Blair as inventors, with Attorney Docket No. A-70543-1/RMA/LM, and under
25 an obligation of assignment to Self Repairing Computers, Inc., San Francisco, Calif.;

 U.S. Provisional Patent Application No. 60/291,767, entitled, "A Self-Repairing Computer," filed May 17, 2001, naming Kenneth Largman and Anthony B. More as inventors, with Attorney Docket No. P-70543/RMA/LM, and commonly assigned to Self Repairing Computers, Inc., San Francisco, Calif.;

- 2 -

U.S. Provisional Patent Application No. 60/205,531, entitled, "Scalable, Diagnostic, Repair and Multi-Use System for Computing Hardware & Devices that Utilize Computer Hardware," filed May 19, 2000, naming Kenneth Largman and Anthony More as inventors, with Attorney Docket No. ZAP 2001-1 and commonly
5 assigned to Self-Repairing Computers, Inc. of San Francisco, California;

U.S. Provisional Patent Application No. 60/220,282, entitled, "Scalable, Diagnostic, Repair and Multi-Use System for Computing Hardware & Devices That Utilize Computer Hardware," filed July 24, 2000, naming Kenneth Largman and Anthony More as inventors, with Attorney Docket No. ZAP 2000-1A and commonly
10 assigned to Self-Repairing Computers, Inc. of San Francisco, California; and

- 3 -

BACKGROUND

Personal-computer manufacturers and sellers often offer via-telephone and on-site repair services. Yet purchasers — particularly home, home-office and small-office purchasers — readily complain that their service contract offers less service
5 than they expected. For example, a computer seller may dispatch a technician only after the purchaser calls the help center, performs a number of tests under the direction of the help center, escalates the problem at the telephone help center and performs redundant or additional tests under the direction of a putatively more knowledgeable telephone-help staff. The purchaser may have to escalate the problem
10 still further and perform additional redundant tests before a repair technician is dispatched.

Frequently, the help center directs the customer to cycle the power on the computer, to re-boot the computer, to detach and reattach peripherals in question and to re-install application and operating-system software. Each call to the help center
15 and each level of escalation may require the purchaser to cycle, re-boot, detach and reattach.

Detaching and reattaching peripherals can be extremely inconvenient. USB devices, for example, typically attach at the back of a computer in a location difficult to reach. In any event, the non-digerati purchaser may fear disassembling his
20 computer, worrying that he may damage the computer further.

Help centers even direct a customer to reformat the boot drive of the computer and re-install operating-system and application software. Re-formatting is an onerous task for several reasons. Firstly, the home, home-office and small-office user rarely reformats a drive in the normal operation of his computer and is unfamiliar with the
25 process itself. Secondly, reformatting destroys all the data on the drive, and such a user understandably becomes anxious on finding out that he will lose all of his data. Thirdly, such a user may not retain the application or operating-system installation media, especially where the seller pre-installs the software. The user may have been unsure which media to keep, or intending to keep a particular media, is in fact unable
30 to locate that media later when needed.

- 4 -

Fourthly, the user typically does not back up his drives as often as an information technologist would recommend. That he will have to rely on his back ups (if any) if he is to have any hope of restoring his application is then not a comforting thought.

5 Accordingly, the art evinces a need for a computer that reduces or even eliminates the need for a user to call a help line, to keep installation media, to attach and reattach peripherals at the port, etc. Indeed, a computer that reduces or eliminates the technical savvy its user needs to effect repairs is desirable.

 These and other goals of the invention will be readily apparent to one of
10 ordinary skill in the art on reading the background above and the description below.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 illustrates a computer incorporating an embodiment of the invention.

Figure 2 is a schematic of a data-store switch according to an embodiment of
15 the invention.

Figures 3A through **3B** illustrate the switch-and-repair process according to one embodiment of the invention.

Figure 4 illustrates the flow of control in a data-store switch according to one embodiment of the invention.

SUMMARY

Herein are taught apparatus and methods for a computer to repair itself.

10 The invention may back up or recover a computing device. The computing device may include a user computing environment and a supporting environment which stabilizes the functionality of the user computing environment. The invention may include one or more external devices or removable media.

- 6 -

DESCRIPTION OF THE INVENTION

OVERVIEW

An example of the invention in use follows: A user runs an application on a computer incorporating an embodiment of the invention. At some point, the user
5 modifies the application or underlying operating system to the point that the application, the operating system or both become unusable. Indeed, the user may no longer be able to even boot the operating system.

Recognizing that the computer needs to be repaired, the user throws a switch on the computer. The computer fixes the malfunctioning software and so informs the
10 user.

The user can then re-boot the computer. On re-booting, the user again has access to a correctly functioning operating system, application and data files.

A SELF-REPAIRING COMPUTER

15 **Figure 1** illustrates a computer **1** incorporating an embodiment of the invention. The computer **1** may include a CPU **10**, volatile memory **11**, peripheral controllers **17, 18**, a first non-volatile data store **12** and a bus **15**, all well known in the art.

The computer **1** may also include switches **13, 19**, a second non-volatile data
20 store **14**, a controller **1A**, a power supply **1B**, an output device **1C** and an input device **1D**.

The bus **15** may communicatively couple the volatile memory **11** and the peripheral controllers **17, 18** to each other and to the CPU **10**. The peripheral controllers **17, 18** may communicatively couple with the data stores **12, 14**,
25 respectively.

The switches **13, 19**, the controller **1A**, power supply **1B**, output device **1C** and input device **1D** may form a data-store switch **1Z**. A data-store switch may alter the accessibility of a connected data store according to the setting of the switch.

- 7 -

The controller **1A** may communicatively couple with the switches **13**, **19**, the output device **1C** and the input device **1D**. The power supply **1B** may supply the controller **1A** (and other switch components) with power. More particularly, the power supply **1B** may power the controller **1A** independently of the power to the rest
5 of the computer **1**.

The power to the switch **1Z** may come from the same source as the power for the rest of the computer (the wall outlet or laptop battery, for example). The switch **1Z** may then be powered from that supply even when the rest of the computer **1** is not. **Figure 10** illustrates this embodiment of the invention.

10 The switch **13** may communicate with the data store **12**. The switch may control (toggle, for example) the identification settings of the data store **12**.

The switch **19** may couple to the data store **14**. The switch **19** may control (toggle, for example) the power to the data store **14**.

The volatile memory **11** may be random-access memory. The data stores **12**,
15 **14** may be magnetic disks, for example.

The output device **1C** may be the monitor of the computer **1**, LEDs or an LCD distinct from the monitor, for example.

Figure 2 is a schematic of the data-store switch **1Z** according to an embodiment of the invention. In **Figure 2**, the opto-isolators **U2**, **U3** implement the switches **13**, **19**, respectively. The Basic Stamp II microcontroller **U1** (from Parallax, Inc., Rocklin, California) implements the controller **1A**. The battery **V3** implements the power supply **1B**. The LCD display port **J1** represents the output device **1C**, and the switches **S1**, **S2** implement the input device **1D**. (Opto-isolator **U4** detects whether the computer **1** has power.)
20

25 In a first mode of operation herein termed "normal mode," the computer **1** may run a predetermined operating system and application. Accordingly, the data store **12** may contain a correctly functioning copy of that software. The CPU **10** may access the data store **12**, boot the operating system and then execute that application.

- 8 -

The data store **12** is termed herein the “boot data store.” The data store **12** may contain a bootable, executable operating system and executable application.

The data-store switch **1Z** may make the data store **12** accessible to the computer **1** as the boot drive (by means of the switch **13**, for example). The data-store switch **1Z** may also make the data store **14** inaccessible to the computer **1** (by means of the switch **19**, for example). Otherwise, the data-store switch **1Z** may idle, waiting for user input on the device **1D**.

In the normal stage, the computer **1** may perform as a conventional computer. The user may run his application software, inattentive to the invention incorporated into the computer **1**.

In a third mode of operation herein termed the “repair mode,” the CPU **10** may run software on the data store **14** and the controller **1A** may execute a program in parallel. A mode intermediate to the normal and repair modes, herein termed the “switching mode,” may effect the transition from normal to repair mode.

In the switching mode, using an input device such as the device **1D** the user may indicate that he wishes to repair software on the data store **12**. (**Figures 3A and 3B** illustrate the switch-and-repair process according to one embodiment of the invention.) In response to the input, the computer **1** may switch from normal operation to repair, step **310**, and repair the software on the data store **12**, step **320**.

The switching of a data store may be logical or physical. Logical switching is switching enforced purely by software. For example, software may set one or more predetermined bits that it or other software tests to determine whether a data store is accessible at any given time.

A physical switch opens or closes a predetermined electrical circuit of a device to be switched. A physical switch may, for example, alter the open/close state of identification jumpers of a data store. A physical switch may turn on or off the power supply to a device to be switched.

Figure 4 illustrates the flow of control in a data-store switch **1Z** according to one embodiment of the invention. On start up, the data-store switch **1Z** may go into

- 9 -

normal mode of operation. In this stage, the switch **1Z** may set the switch **13** to make the data store **12** the boot drive, step **4A3**. The switch also may set the switch **19** to leave the template data store **14** unpowered.

5 The data-store switch **1Z** may then idle, waiting for the user to initiate the switch to repair mode, step **4A5**. The data-store switch **1Z** may display a message indicating that it is in normal mode, step **4A1**.

When the data-store switch **1Z** receives an indication to switch to repair mode, the switch **1Z** may ask the user to confirm this indication, step **4B5**. Confirmation is preferable where the repair process is destructive before it is constructive.
10 Confirmation is preferable also because the activation of the input device indicating the switch to repair mode may have been accidental or ill considered.

On confirmation if requested, the data-store switch **1Z** may switch power to the data store **14**, step **4B9**, making the data store **14** accessible to the computer **1**. The data store **14** may be permanently configured to be addressable as the boot drive
15 when it is accessible. Accordingly, the address of the data store **12** may then change.

In normal operation, the data store **12** may be addressable as the boot drive. However, during the switch, the switch **1Z** may change the identity (address jumpers, for example) of the data store **12** to something other than the boot-drive identity.

The computer **1** is now ready to enter the repair stage.

20 Switched physically to repair mode, the computer **1** may boot from the template boot drive. The booted program or some other program executed during the boot sequence (autoexec.bat, for example, on machines running Windows™ operating system from Microsoft Corp., Redmond, WA) may query the user.

In one embodiment, on rebooting the computer **1** may automatically repair the
25 data drive **12**. It copies software from the template data store **14** to the data store **12** without further direction from the user. Previously set user preferences may, however, direct the course of repair.

Thus, where the template data store **14** contains only application software, the repair process may copy over or re-install that application software from the template

- 10 -

data store 12. Where the template data store contains operating-system and application software, the repair process may copy over or re-install the operating system first and then the application software.

Uninstallation or deletion of an application may precede re-installation or
5 copying over of that software. Re-formatting of the data store 12 may precede re-installation or copying over of the operating system. Resetting of ROM-resident parameters may precede re-installation or copying over of operating-system or application software.

On completion of the repair, the repair software may direct the user to switch
10 back to normal mode and re-boot the computer 1.

Alternatively, the repair process may be menu-driven. The repair process may present the user a sequence of options to determine what repair process to execute. For example, on re-boot in repair mode, the repair software may offer the choices of running the repair process, reviewing repair-process settings, updating the template
15 software (the application, operating system or repair-process software itself) and quitting the repair process.

The template data store 14 may contain application software, operating-system software and repair-process software. The application software may include the executable software itself (.exe, .dll, .o, etc.) or the files created by the application
20 (.wpd files for Corel WordPerfect word-processing software, for example).

The software on a template data store 14 typically is an operating system and may include one or more applications, along with the underlying software to run the operating system (and any included application) on a computer with a predetermined configuration. The underlying software may include one or more boot records, one or
25 more partition tables or a BIOS.

The template software is created by installing software onto a data store, by copying installed software onto the data store or by copying installation software onto a data store. (Installed software includes data files and other pre-existing software.)

- 11 -

The template data store software may be updated. Where the template software is installation-ready software, that installation software may be updated to a different, usually later, version. Where the template software is a backup of the software on the data store 12, a different, usually more recent, backup of the data-store software replaces or supplements that software.

Repair-process settings may include whether to recover data, run a virus check, reformat the data store, revert to a backup, run a human-mediated (i.e., manual) or an automatic repair, run diagnostics (software or hardware, for example). Repair-process settings may also include whether to format and at what level (quick versus low-level, for example), what software to re-install (operating system (OS) only; OS and executable-application software; OS, executable-application software and application data files; data files only, for example), whether to switch automatically (i.e., under program or hardware control), what level of repair to run (quick, better or best, in one embodiment), whence to setup (backup or template, in one embodiment) and whence to recover data files (most recent backup prior to repair, backup at the time of repair, other predetermined backup, query-and-response-specified backup, as examples).

The repair process may entail recovering a usable version of the appropriate data file. In some instances of computer repair, the problem is not so much with the operating-system or executable-application software so much as with the files (usually data files) associated with one or more of the applications. If the application in question is Microsoft Outlook, then the file to be recovered may be the mail-and-folder-data .pst file. Where the application is Microsoft's Internet Explorer, the file to recover may be the favorites file.

Running a virus check may entail first checking that the virus-check-and-repair software is up to date. Because new software attacks appear daily, and because newer malicious code has a higher chance of delivering a payload, this is not a trivial step. The software may then check for malicious code and repair software, as directed by the user or by default.

- 12 -

The above process presupposes that the data store **14** contains a copy of (a version of) the operating-system, application software or data file on the data store **12**. In this sense, this second data store **14** is termed herein the "template data store." With the computer **1** switched to boot from the template data store **14**, the
5 computer **1** may perform the original copying of template software onto the data store **14**. (Where the data store **14** is a read-only medium, it may arrive at the computer **1** in a pre-written state.)

An example of the operation of the computer **10** follows: Assume that the data store **12** contains a bootable Windows™ operating system (from Microsoft
10 Corp., Redmond, WA). Assume also that the data store **12** also contains NaturallySpeaking® application software (Lernout & Hauspie, Ieper, Belgium and Burlington, MA).

The operating system and the application on the data store **12** may have each been run any number of times, and the user may have customized the operating
15 system, the application or both to his preferences. In contrast, the template data store **14** may contain as-installed copies of the operating-system and the application software.

In the course of using his computer **1**, the user puts the computer **1** into an undesirable state. He may, for example, foul up the optional settings of the operating
20 system or application such that he cannot reset them to a usable state. He may download a virus, Trojan horse or other malicious code that changes his operating system, application or both. The particulars of the malicious code are unknown but the manifest effect is that the computer **1** is partially or completely inoperable. He may remove files critical to the correct operation of the software. As one of skill in
25 the art will recognize, the ways in which software may be intentionally or unintentionally altered to the point of unusability are legion.

Recognizing that his computer **1** is in an undesirable state, the user activates the switch **13**, step **300**. **Figure 3** illustrates the switch-and-repair process according to one embodiment of the invention, and step **310** illustrates the actual switching. In

- 13 -

response to the switch activation, step 300, the computer 1 repairs the software on the data store, step 320.

The repair process involves copying software from the template data store 14 to the data store 14. The software on the template data store 14 may be a master copy, a backup copy or an archive copy of software on the data store 12. (An archive is a copy of software, which copy cannot be overwritten or deleted.)

With template software on the template data store 14, the computer 1 may re-install or copy over software onto the data store 12. The computer 1 may overwrite all or part of any software on the data store 12.

The computer 1 may offer the user options as to how thorough its attempt to repair itself should be. In one embodiment, the computer 1 offers the options of a "Quick Repair," a "Better Repair," a "Best Repair" and a "Test." A Quick Repair may, for example, re-install or copy template software from the data store 14 onto the data store 12 without first re-formatting the data store 12. The Better Repair may perform a high-level re-format of the data store 12 before that copy or re-installation. A Best Repair may perform a low-level re-format of the data store 12 before copying over or re-installing software.

Figure 4 illustrates the switch-and-repair process in more detail, according to one embodiment of the invention. The switching copies software from the template data store onto the data store, replacing the unusable software on the data store.

A number of situations occur where the computer 1 may effect repair without rebooting. For example, if only data files or application executables need to be repaired, then shutting down the operating system booted from the data store 12 is not usually necessary — especially in newer operating systems such as Windows 2000 (Microsoft) and more sophisticated operating systems such as Linux .

Further, a large number of operating-system files can be repaired (for example, by replacement) without shutting down the operating system. Repairing the operating system without rebooting is a preferred embodiment.

- 14 -

Still further, for backups (automated or otherwise), continuing to run from the data store already booted may be preferable. Where the computer 1 can become sufficiently quiescent that a backup from the data store 12 to the data store 14 can occur while still booted from the data store 12, then such a backup is quicker than
5 shutting down and backing up the data store 12 while booted from the data store 14.

Where the data store 12 remains the boot drive when the data store 14 is simultaneously available, the data store 14 may be addressable as other than the boot drive. The address of the data store 14 may be switched similarly to the address switching of the data store 12.

10

A VIRUS AND HACKER-RESISTANT COMPUTER

Figure 6A illustrates a computer 6 incorporating an embodiment of the invention. The computer 6 may include a CPU 60, volatile memory 61, peripheral controllers 67, 68, first and second non-volatile data stores 62, 64, data port 69,
15 communications link 6A and buses 65, 66, all well known in the art. The computer 6 may also include a data-store switch 6Z.

The bus 65 may communicatively couple the volatile memory 61, the peripheral controllers 67, 68 and the data port 69 to each other and to the CPU 60. The peripheral controllers 67, 68 may communicatively couple with the data stores
20 62, 64, respectively. The data port 69 may mediate access to the communications link 6A.

The bus 66 may communicatively and electrically couple the peripheral controller 67 to the data store 62 and to the boot-store switch 6Z. More specifically, the boot-store switch 6Z may switch the power line 661 of the bus 66, thus powering
25 up or down the boot store 62.

Likewise, the bus 67 may communicatively and electrically couple the peripheral controller 68 to the data store 64 and to the boot-store switch 6Z. The boot-store switch 6Z may switch the power line 671 of the bus 66, powering up or down the boot store 64.

- 15 -

The port 69 may link the computer 6 to other devices such as a modems, networks, etc. as indicated by the communications link 6A.

The computer 6 may operate in two states: Connected and Disconnected. In the Disconnected state, the computer 6 does not use the data port 69 to communicate
5 and the data-store switch may enable the data store 62.

By contrast, in the Connected state, the computer 6 may use the data port 69 to obtain data over the communications link 6A. In the Connected state, the switch may enable the second data store 64.

Thus, the computer 6 may enable only one of the multiple data stores 62, 64 at
10 any given time, which depending on whether it is accessing the communications link 6A. This isolates data received over the communications link 6A to one of the data stores, namely, the data store 64. Where the data received was maliciously created (a virus or a hacking executable), this data is confined to the data store 64.

The switching of the data stores 62, 64 may be done under manual, hardware
15 or software control. A mechanical throw switched by the user when the user wishes to access (or cease accessing) the communications link exemplifies a manual switch. A boot-store switch 6Z that responds programmatically to the CPU 60 illustrates a software-controlled switch.

For example, if the user boots an Internet browser and the communications
20 link 6A is the Internet, then the CPU 60 may programmatically recognize the (intended) launch of a browser and initiate the switch of the data stores 62, 64. The switch may involve re-booting the computer 6 in order to make the second data store 64 the only data store available during the use of the communications link 6A. (A browser on the data store 64 may launch automatically on the boot from the data
25 store 64.)

In one embodiment, the computer may synchronously switch the port 69 and the second boot store 64. This may improve the resistance of the computer 6 to hacking or infection.

- 16 -

Figure 6A illustrates the enabling of the data store **62** in conjunction with the defeat of access to the communications link **6A**. The solid line continuing the power line **661** through the boot-store switch **6Z** illustrates the accessibility of the data store **62**. Conversely, the dashed lined through the switch **6Z** illustrates the inaccessibility of the data store **64**.

Figure 6B illustrates the enabling of the data store **64** in order to support access to the communications link **6A**. The solid power line through the boot-store switch **6Z** illustrates the accessibility of the data store **64**. Conversely, the dashed lined through the switch **6Z** illustrates the inaccessibility of the data store **62**.

The data store **64** may contain application software to process the data received over the link **6A**. In such a setting the need to migrate the data on the data store **64** to the data store **62** may be minimal or non-existent.

Where, however, the application to process the data received over the link **6A** and stored on the store **64** resides on the data store **62**, then a process of migration is necessary. A predetermined time after receiving data over the link **6A**, the computer may simultaneously enable the data stores **62**, **64** and copy the data received to the data store **62** for processing there. The delay allows, for example, anti-virus software providers to produce and distribute security software addressing threats that have come to light since the time of receipt of the data.

The migration process may be manual or automatic.

A LOCKABLE NETWORK COMPUTER

Figure 7A illustrates a computer **7** incorporating an embodiment of the invention. The computer **7** may include a CPU **70**, volatile memory **71**, a peripheral controller **77**, a non-volatile data store **72**, a data port **79**, a communications link **7A** and buses **75**, **77**, all well known in the art. The computer **7** may also include a switch **7Z**.

The bus **75** may communicatively couple the volatile memory **71**, the peripheral controller **77** and the data port **79** to each other and to the CPU **70**. The

- 17 -

peripheral controller **77** may communicatively couple with the data store **72**. The data port **79** may mediate access to the communications link **7A**.

The bus **77** may communicatively or electrically couple the data port **79** to the communications device **7B**.

5 The port **79** may link the computer **7** to other communicators through a communication device **7B** and over a communications link **7A**. Examples of the communications device **7B** and link **7A** include an acoustic modem **7B** and a POTS telephone line **7A**; a tap **7B** and an ethernet **7A**; and a wireless modem **7B** and radiation-permeable space **7A**.

10 The switch **7Z** may switch a power line **771** of the bus **77**, thus powering up or down the communications device **7B**. The switch **7Z** may switch (tri-state, for example) a data line **771** of the bus **77**, thus interrupting or enabling the ability of the communications device **7B** to transfer data to the data port **79**.

15 The computer **7** may operate in two states: Network Connected and Network Disconnected. **Figure 7A** illustrates the computer **7** in its Network Disconnected state, while **Figure 7B** illustrates the computer **7** in its Network Connected state. (The solid line continuing the power line **761** through the switch **7Z** illustrates the continuity of the power or data line **771**, and dashed lined through the switch **7Z** illustrates the discontinuity of that line **771**).

20 In the Network Disconnected state, the switch **7Z** may disconnect the communications device **7B** from communicating on the data port **79**. Accordingly, none of the software running on the computer **7** may access the communications link **7A**.

25 By contrast, in the Network Connected state, the switch **7Z** may enable the communications device **7B** to communicate on the data port **79**. Accordingly, software on the computer **7** may access the communications link **7A**.

An exemplary use for the computer **7** is where a parent uses the computer **7** to access, say, his employer's computer network via a virtual private network (VPN) over the Internet **7A**. The parent also wants his child to be able to use the computer **7**

- 18 -

for school or recreation — but without access to the Internet 7A. The parent thus switches the computer 7 into the Network Enabled state when he (the parent) wants to use it, and switches the computer 7 into the Network Disconnected state when the child is to use the computer 7.

5 The switching of the data stores 72, 74 may be done under manual, hardware or software control. A mechanical switch thrown by the user when the user wishes to access (or cease accessing) the communications link 7A exemplifies a manual switch. A mechanical switch that may be locked with a key, for example, is preferable.

10 A switch 7Z that responds programmatically to the CPU 70 illustrates a software-controlled switch 7Z. (The CPU 70 may respond to any kind of input, including keystrokes, voice commands, biometric data and data received over a network.) A hardware switch 7Z may be considered as an analog computer.

15 A computer 7 running an operating system that supports hot swapping offers an advantage. The addition and removal of the communications device 7B from the computer 7 may confuse OSs that do not permit hot swapping of peripherals.

A MULTI-DATA STORE SERVER

20 **Figure 8** illustrates a computer 8 incorporating an embodiment of the invention. The computer 8 may include a CPU 80, volatile memory 81, a peripheral controller 87, multiple non-volatile data stores 82a, 82b, ... 82α, a data port 89, a communications link 8A and a bus 85, all well known in the art. The computer 8 may also include a data-store switch 8Z and a bus 86 consisting of the buses 861 or 862.

25 The bus 85 may communicatively couple the volatile memory 81, the peripheral controller 87 and the data port 89 to each other and to the CPU 80. The data port 89 may mediate access to the communications link 8A.

30 The peripheral controller 87 may communicatively couple with the data-store switch 8Z. The data-store switch 8Z in turn may communicatively or electrically couple to the data stores 82. The bus 861 may communicatively couple the data path of the switch 8Z to those of the data stores 82, and the bus 862 may electrically couple a power supply in or through the switch 8Z to the data stores 82.

- 19 -

The data port **89** may mediate access to the communications link **6A**. The port **89** links the computer **8** to other communicators over the communications link **7A**.

The computer **8** may operate in any of N states, where N is the number of data stores **82**. In a first state, the data-store switch **8Z** enables the first data store **82a** to
5 communicate with the peripheral controller **87**. In the second state, the switch **8Z** enables the second data store **82b** to communicate with the peripheral controller **87**, and in the N th state, the switch **8Z** enables the N th data store **82 α** to communicate with the peripheral controller **87**.

The corruption or other failure of the data store **82** currently communicating
10 with the controller **87** prompts the switching from one state to another, and thus from the failed data store to another, working data store **82**. (The failed data store **82** may then be repaired in place, or it may be removed and repaired, removed and replaced, or removed permanently.)

Where, for example, the computer **9** is a web server and the communications
15 link **8A** is the Internet, the multiple data stores **82** may provide resistance against infection and hacking by malicious users of the Internet **8A**. If the hackers succeed in corrupting the data store currently attached to the peripheral controller, then a switching may occur from that corrupted data store **82** to another correct data store **82**. This switching may occur very quickly (preferably as quickly as possible) in
20 order to minimize the loss of access to the data on the data stores **82**.

The switching may be manual, hardware or programmatic. For example, a diagnosis program may execute periodically to determine the health of the currently accessible data store **82**.

25 **A COMPUTER WITH PERIPHERALS THAT CAN BE CYCLED**

Figure 9A illustrates a computer **9** incorporating an embodiment of the invention. The computer **9** may include a CPU **90**, volatile memory **91**, a controllers **97, 98**, a non-volatile data store **92**, a port **99**, a peripheral **9B** and buses **95, 97**, all well known in the art. The computer **9** may also include a switch **9Z**.

- 20 -

The bus **95** may communicatively couple the volatile memory **91**, the controllers **97**, **98** to each other and to the CPU **90**. The controller **97** may communicate with the data store **92**. The controller **98** may communicate with the peripheral **9B**.

- 5 The bus **97** may communicatively or electrically couple the port **99** (and thus the controller **98**) to the peripheral **9B**.

The peripheral **9B** may be any computer peripheral. Examples include printers, USB devices, scanners, fax machines, data stores and keyboards.

- 10 The switch **9Z** may switch a power line **971** of the bus **97**, thus powering up or down the peripheral **9B**. The switch **9Z** may switch one or more data lines **972** of the bus **97**, thus disabling or enabling the peripheral **9B** to transfer data to the port **99**.

A user of the computer **9** may be using the peripheral **9B**, transmitting or receiving data on the from the device **9B** as expected. The switch **9Z** is supplying power to the peripheral **9B**.

- 15 At some point, the computer **9** becomes unable to communicate with the peripheral **9B**. This may be caused by an error in the software or hardware of the computer **9**, including software or logic of the peripheral **9B**.

- 20 The user attempts to revive communications with the peripheral **9B**. The user may, for example, cycle the power to the peripheral **9B**. Thus, the user changes the state of the switch **9Z** such that the switch **9Z** goes from powering to the peripheral **9B**, to not powering that peripheral **9B**, to again powering that peripheral **9B**. This switching may be done manually, in hardware, or programmatically.

- 25 The cycling of the peripheral **9B** may resolve the communication problem that the user was experiencing. For example, where the problem was with the software or logic of the peripheral **9B**, then the power cycling may clear the software or logic state of the peripheral **9B**. Where the problem was with the software or logic of the computer **1**, cycling the power may clear the software or logic state of the controller **97** or applications running in the memory **91**.

- 21 -

Figure 9B illustrates an alternate embodiment of the computer **9**. The switch **9Z** switches both power and data lines.

A MULTI-USER COMPUTER

5 **Figure 5** illustrates a computer **5** incorporating an embodiment of the invention. The computer **5** may include a CPU **50**, volatile memory **51**, a peripheral controller **57**, multiple non-volatile data stores **52a**, **52b**, ... **52α** and a bus **55**, all well known in the art. The computer **5** may also include a data-store switch **5Z** and a bus **56** consisting of the buses **561** or **562**.

10 The bus **55** may communicatively couple the volatile memory **51**, the peripheral controller **57** and the data port **59** to each other and to the CPU **50**.

 The peripheral controller **57** may communicative with the data-store switch **5Z**. The data-store switch **5Z** in turn may communicatively or electrically couple with the data stores **52**. The bus **561** may communicatively couple the data path of
15 the switch **5Z** to those of the data stores **52**, and the bus **562** may electrically couple a power supply in or through the switch **5Z** to the data stores **52**.

 The computer **5** may operate in any of N states, where N is the number of data stores **52**. In a first state, the data-store switch **5Z** enables the first data store **52a** to communicate with the peripheral controller **57**. In the second state, the switch **5Z**
20 enables the second data store **52b** to communicate with the peripheral controller **57**, and in the Nth state, the switch **5Z** enables the Nth data store **52α** to communicate with the peripheral controller **57**. Only one data store **52** may access the peripheral controller **57** at any given time.

 In one embodiment, the computer **5** has only one controller with multiple
25 devices. In another embodiment, the computer **5'** has multiple controllers, each with respective multiple peripherals. The switching then switches among the multiple peripherals of the first controller, the multiple peripherals of the second controller, etc. (The multiple controllers need not have the same number of multiple peripherals.)

- 22 -

Each data store **52** may contain self-contained software for a respective user or group of users. Each data store **52** may contain a bootable operating system, and optionally such application or data files as the user(s) corresponding to the data store **52** may require or desire.

5 Each user or group of users may use only a predetermined one (or more) of the data stores **52**. Thus, before using the computer **5**, a user sets the switch **5Z** to the predetermined position enabling the data store **52** corresponding to that user to communicate via the controller **57**.

10 In this way, a first user's data is separated from a second user's data on the same computer. The computer **5** more effectively separates users' data by enforcing security at a physical level rather than at the logical (software-enforced) level typical of multi-user operating systems.

15 In this scenario, re-booting between switches is desirable. Re-booting clears out the memory **51** in the switch from one user to another. Also desirable is a multi-key, multi-position lock. Any one key may turn the lock to any one predetermined position, enabling one corresponding data store **52**.

20 The invention now being fully described, one of ordinary skill in the art will readily recognize many changes and modifications that can be made thereto without departing from the spirit of the appended claims. For example, in addition to switching software, data stores or other peripherals as described above, a computer may also switch properly functioning hardware for malfunctioning hardware. Indeed, in a computer with multiple mother boards, a switch may switch the functioning components of a computer from one board to another.

25 Also, while the description above usually uses data stores as the devices to switch, one of skill in the art will readily now realize that other computer components may be switched, including logic boards, ROM and controllers.

30 Under certain circumstances, danger or damage may follow from switching when power is supplied. Accordingly, a switch may be deactivated when such danger or damage may result. Logic such as the controller **1A** may prevent dangerous or damaging switching by tracking power states, device identities, etc. and permitting

- 23 -

switching, for example, when no electrical current is flowing to the devices to be switched.

Preferably, the switch is located in an easy-to-reach location. This contrasts with the typical location of USB, keyboard and other ports, for example.

5

On-The-Fly Repair Of A Computer

The following invention provides an apparatus and method of supporting the backup and recovery of a computing device. The computing device will typically include both a user computing environment and a supporting environment which
10 enhances the stability and functionality of the user computer environment.

Processes

In one embodiment, a plurality of computing processes may be utilized to enable the On-the-Fly invention. Here, individual computing processes may monitor,
15 track, predict the stability, backup, restore, or recover attributes within the user computing environment. The attributes may be software specific, data specific, operating system specific, or any combination. Utilization of the plurality of computing processes can facilitate the normal operation of the user computing environment. In one embodiment the user computing environment may be stabilized
20 without user intervention such as requiring the user to shut-down, restart, logging off, logging on, or terminating applications. In one embodiment the supporting environment may have a capability interacting with the user computing environment. In one embodiment the supporting environment may be capable of initiating or causing the user computing environment to shut-down, restart, logging off, logging
25 on, or terminating applications.

Different Computing Systems

In one embodiment the user computing environment and the supporting environment function in different computing systems. The two computing systems

- 24 -

may reside in a common box. The user computing system may consist of data storage devices, RAM, processor, video card, and other attributes known in the art to facilitate a computing system. The supporting computing system may consist of a master template data storage device, RAM, processor, and other attributes known in the art to
5 facilitate a computing system. In one embodiment, the data storage devices may be linked as needed to perform repairs. Such as, the need to copy data from the support environment to the user environment.

Snap-Shot of Data

10 In one embodiment, the present invention takes a snap-shot of the user computing environment. This snap-shot may subsequently be utilized to restore, analyze, or enhance the stability of the user environment. The snap-shot may include a stable image of the operating system, software applications, or user data. The snap-shot may contain an idealized or stable version of a disk drive utilized by the user
15 environment, or a subset of the disk drive such as an individual partition. The snap-shot may also include an idealized version or image of the user system RAM, user system disk drive, user system partition image, memory of the video card, or any other memory stored or utilized in the user computing environment. These snapshots may be stored in the associated support environment data storage device

20

Monitoring

The supporting environment may monitor the user environment. The monitoring may include monitoring of processes running or enabled within the user environment. The monitoring may include monitoring both the utilization of the data
25 storage device, data contained on the data storage device, and other aspect necessary for the normal operation of the user environment. This monitoring may facilitate identifying undesired changes, potential problems and also potential solutions. The supporting system may detect a freeze or other undesirable change within the user environment.

- 25 -

Recovery

When an undesirable change is detected in the user environment, the supporting environment may attempt to recover or restore or repair the user environment. The supporting system may be capable of re-enabling the user environment in a number of ways, such as resetting the keyboard in the event the keyboard locks the communication of keystrokes to the user environment. Further recovery of the user environment may be supported by reset connections such as describe by "Freezebuster", reset and clear devices as needed, replace defective software components as needed, and/or switch hardware components and/or devices as needed. The supporting environment and or supporting system may copy all or part of the data from one or more of the idealized snapshots mentioned above. These snapshots may be copied into their respective devices and/or locations.

Application Configuration

Another embodiment supports an ability to run two or more different programs at the same time on one computing system where the data and applications may be isolated from one another but may share output and/or input devices. In one embodiment, the applications may be isolated by executing the applications in a separate address space. The applications and data may be further isolated by utilizing two separated data storage devices. In order to safely send a command from one isolated data storage device to the other isolated data storage device the following may be utilized. In one embodiment, when an icon on the desktop icon is clicked the following may occur. The icon may execute a command that would launch a specific application on the other isolated data storage device. This may be accomplished by a shared ASIC that sends the command to the other isolated data storage device.

Another embodiment involves isolation of data with merged display. In this embodiment two user environments can be separated for the purposed of isolating data. For the AntiHacker System: A hard drive that does not contain "sensitive" data could be isolated and attached to a network. A second hard drive, may or may not be attached to the other hard drive (in any way), could be utilized for "sensitive" user

- 26 -

data, but have no exposure to the network because it is "isolated" by a means of switching. The video signals associated with the data coming from these two hard drives could then be "merged" onto the same screen. In other words, all of the computing would be happening within isolated "secure zones" within a single
5 computer but would not appear so to the user. Another example: the anti-virus system could use this method to isolate potentially infectious data.

Application Output

Applications may have its output displayed on the same screen alongside
10 and/or superimposed upon the same screen with other applications and data that were being "computed" separately. Both computing processes may be separated but may then be "merged" together on the screen, and/or overlaid one another on the same screen. In one embodiment, this may be achieved by using multiple video cards. This concept can be applied for example to the Repair System, Multi User, Anti-Hacker,
15 anti-theft and Anti-Virus.

In another embodiment both the user computing environment and the supporting environment will reside on a single computer system. A snap-shot of the operational user environment will be taken. The snap-shot will be associated with the supporting environment. Processes associated with the supporting environment will
20 monitor the activities and status of the user computing environment. The monitoring function will become aware of any degraded performance of the user computing environment, such as a system freeze up. The monitoring function notifies the supporting environment of any degraded performance. The supporting environment will perform any recovery action as necessary to recover or restore the user
25 environment. Recovery may include utilizing the snap-shot to recover or restore the user environment. An entire user disk may be restored. A specific application or software package may be restored, or particular files.

- 27 -

External Repair Of A Computer

The invention may back up or recover a computing device. The computing device may include a user computing environment and a supporting environment which stabilizes the functionality of the user computing environment. The invention
5 may include one or more external devices or removable media.

Master Template

A master template may be a copy of data that represents an ideal state of a computer system or component of a computer system. The master template may be
10 created by copying data from an operational computer system or component of a computer system. The computer system may be in an ideal state before creating a master template. An ideal state of a computer system may be represented by data that is accessible to the computer system. Data, within this context, may include an operating system (e.g., Linux, Unix, Windows 98), applications (e.g., WordPerfect,
15 Microsoft Office), user data (e.g., operating system preferences, background images, created documents), and component data (e.g., BIOS, PRAM, EPROM). Data may also include any information accessible to the computer system, including local and remote data storage devices.

As an example, the master template for one computer system may include all
20 of the information installed on that computer system, such as Windows 98 operating system, WordPerfect application, documents created by the user. The information may be installed across multiple hard drives accessible to the computer system. Additionally, the master template may include a copy or an ideal-state version of the BIOS settings.

25 A master template may represent a snapshot of a newly purchased computer system. The system is typically in an ideal state with an operating system and various applications pre-installed, thereby allowing a user to begin utilizing the computer system. For a particular user, the master template may represent an ideal state of a computer system, including, for example, an operating system, applications, and user

- 28 -

customizations. A user customization may include the users prior selection of a picture or “.jpg” image for a desktop background, such as a picture of the users pet.

Optionally, the master template may be created from a first computer system and subsequently may be used as a master template for a different computer system.

- 5 An ideal state of the first computer is thereby transferred to a second computer system or any number of computer systems.

Backups

- 10 A backup is a copy of data that represents an information on a computer system or component of a computer system. The backup may be created by copying data from an operational computer system or component of a computer system. A backup of a computer system may include data that is accessible to the computer system. Data, within this context, may include an operating system (e.g., Linux, Unix, Windows 98), applications (e.g., WordPerfect, Microsoft Office), user data
15 (e.g., operating system preferences, background images, created documents), and component data (e.g., BIOS, PRAM, EPROM). Data may also include any information accessible to the computer system, including local and remote data storage devices.

- 20 As an example, a backup for one computer system may include all of the information installed on that computer system, such as Windows 98 operating system, WordPerfect application, documents created by the user. The information may be installed across multiple hard drives accessible to the computer system. Additionally, the backup may include a copy or an ideal-state version of the BIOS settings.

An archive is a backup which typically may not be erased.

25

Data Storage Device

A data storage device includes memory devices, which are accessible to a computer system. A computer system is capable of accessing or storing data in a variety of memory devices. Memory device may include hard drives, RAM, ROM,

- 29 -

EPROM, or BIOS. Memory devices store data (e.g., data or programs). User data is typically stored on disk drives, but may potentially be stored on any memory device. Typically, a computer system utilizes a variety of memory devices. For example, an operating system, applications and user data may be stored on a hard drive, a BIOS
5 program may be stored in ROM, and BIOS data may be stored in a protected memory.

DSD

A “DSD” refers to a “data storage device.”

10 Methods of External Attachment

Data Storage Device (DSD) may be an external device. A variety of protocols currently exist for utilizing external devices. Some of the more prevalent protocols include TCP/IP, USB, USB 2, Firewire, IEEE 1394, PS/2, parallel, serial, PCMCIA, SCSI. Other protocols and method of connecting external devices to a computer
15 system will be apparent to one skilled in the art. As an example, a SCSI hard disk and SCSI CDROM are memory devices that may be attached to a computer system. The computer system may then read or write to the external device.

Repair Process:

20 An automated process may repair a data storage device of a computer system. The repair process may include multiple programs. The automated process may be triggered by a particular event or a set of events. The repair process may be specific to a particular data storage device such as the primary boot partition of a hard drive. The repair process may encompass a variety of functions which may be modified,
25 added, of skipped based on the type of repair or user preferences. The user may modify user preferences.

In one embodiment, the repair process represents a sequence of functions. Typically a Master Template is either provided to the user or created by the user.

- 30 -

Backups are created intermittently. The computer system becomes unstable and repair becomes necessary. The user may activate the repair process or the repair process may recognize the instability or problems with the system and activate the repair process.

5 Prior to repair, a Master Template typically exists for the computer system. The Master Template may have been created in a number of different ways. Several ways of creating one or more Master Templates for this computer system include: shipped with a new computer, created with the installation of software (e.g., software to support this process), created by a user-activated program, periodically created of a
10 Master Template by a program.

 Backups typically exist for a computer system. A backup may include user data and programs which have been stored on a data storage device accessible to the computer system. For example, documents may have been created or modified by a user. These documents may be stored as a backup. The user may have installed
15 additional programs that may be stored in a backup.

 During a backup process data is copied from a data storage device of the computer system to the backup data storage device(s). Any data that is accessible to the computer system may be backed up. The backup may be compressed. Compression may reduce the amount of storage space required to hold the backup.
20 Incremental backups may also be used. Incremental backups may reduce the time required to perform a backup and reduce the storage space required to store them. Backups may be stored as archives.

Repair Process is activated and (Optionally may be confirmed):

25 The repair process may include a number of functions. The repair process may be initiated by a user, administrator, repair software, or repair hardware. The user may specifically initiate the process (e.g., double clicking on an icon of a graphical operating system). An administrator may initiate the process by communicating with the computer system over an internet connection such as TCP/IP. Repair software
30 may initiate the process by utilizing a boot diskette or a separate boot partition on the

- 31 -

hard drive. Repair hardware may initiate the process by sensing a frozen state of the operating system or hard disk, and subsequently initiating the repair process. Alternatively, the user may press a hardware switch which initiates a process to shutdown the machine, switch boot disks, and the subsequent startup may initiate the
5 continuation of the repair process.

The repair process may be configured to allow the user to confirm the repair process in a number of scenarios. For example, before a DSD is reformatted the user may be requested to confirm the operation. The user may be allowed to halt the repair process.

10 The repair process may utilize a Master Template, Backup, Archive, various commands associated with an operating system, switching, and other programs, for repairing a computer system. For example, the repair process may format and partition a hard disk using an MS-DOS command, then copy a Master Template to the primary boot partition of the hard drive, then copy the latest Backup or Archive, then
15 mark the primary boot partition as the active partition.

Any number of backups or archives may be used to restore the user DSD(s).

Command associated with an operating system may be used to reset or update DSD of the computer system. A DSD (e.g., PRAM, BIOS, or CMOS) may be updated through the use of commands associated with an operating system.
20 Typically, MS-DOS commands may be used to download, save, reset, reset to the default, or update a BIOS version. For example, one step in the repair process may include booting into an MS-DOS partition, executing MS-DOS commands to update the BIOS of the computer system, then change the boot device and reboot the computer system to continue the repair process if necessary. Alternatively, the DSD
25 (e.g., BIOS) may be set to a previously saved state. The previously saved state may be included as part of the Master Template, Backup, or an Archive.

The repair process may also be capable of managing DSDs. Managing DSDs may include testing, reformatting, analyzing, resetting, or determining bad blocks. Alternatively, the repair process may interact with other programs to provide
30 management functionality of all or some DSDs. For example, the repair process may

- 32 -

rely on operating system commands to format a DSD (e.g., a hard drive), but interact with a program to interact with another DSD (e.g., BIOS, PRAM).

The repair process may evaluate the present state of the computer system. As part of the analysis the repair process may determine or recommend a type of repair.

5 For example, if the DSD (e.g., hard disk) is not responding then reformatting may be recommended. If only several files appear to be corrupted then the repair process may determine only those files need to be copied from a Master Template or a backup. Some or all of the data from a master template may be copied on to the DSD(s). Alternatively, the repair process may copy the entire master template to the

10 DSD(s).

The repair process may perform a similar evaluation regarding how much of a backup needs to be copied. Some or all of the data from a backup may be copied on to the DSD(s). Alternatively, the repair process may copy the entire master template to the DSD(s).

15 Rebooting the computer system may be integrated into the repair process. Switching between boot devices may be integrated into the repair process. The repair process may switch the boot disk from hard disk 1 to hard disk 2. Power may be cycled such that hard disk 2 boots up as the active partition. A default program may be executed as part of the boot sequence to perform part of the repair process.

20 Subsequently, the repair process may alter the hard disk 1, switch hard disk 1 to the active partition, and then reboot or cycle the power to initiate the booting of hard disk 1.

Some Exemplary Embodiments of External Device Embodiments

25 The repair process may be initiated or managed by an externally located device that may be communicative coupled to the computing device through, e.g., USB, Firewire, parallel, serial, PS/2, PCMCIA, or infrared. The external device may be the boot device.

- 33 -

An external boot device may be connected to the computer system with the boot device activating the repair process. The repair program may reside on the boot device or a second data storage device. The second data storage device may also be communicatively coupled to the computer system. The second data storage device
5 may contain master templates, backups, or archives. The second data storage device may also contain the repair program or other programs which facilitate the repair process.

For example, an internal SCSI device "id 0" may be the default boot device. The repair process may switch the power to the SCSI device "id 0" OFF. The repair
10 process may switch the power to an external SCSI device "id 0" ON. The repair process reboot the computer system by actuating a reset command (e.g., a mechanical device, a logic circuit). When the computer system reboots, the external SCSI device may be the boot device. The repair process may then continue as directed by part of the repair process on the external SCSI hard drive.

15 The repair process may include switching the device id's of a primary and secondary SCSI disk. In this second example, the internal SCSI drive may be "id 0" and the external SCSI drive may be "id 5". The repair process may change the internal SCSI device to "id 5" and the external SCSI device to "id 0". Switching of the SCSI device id's may be performed by the repair process (e.g., a mechanical
20 device or a logic circuit, activated by the repair process).

In another embodiment, the BIOS may be modified to enable booting from an external device. The boot device may also be switched by updating the BIOS. Typically the BIOS defines the boot sequence. If the first boot device is not found, then an alternate boot device may be defined in the BIOS (e.g., the boot-device
25 sequence is CDROM, A:, C:). The BIOS may be downloaded, modified, and restored. The BIOS may be updated (e.g., in place, via download-modification-upload) to change the boot identifier of a USB device, an IDE device, or other devices. The repair process may download a copy of the BIOS in a variety of ways. One example, includes booting into an MS-DOS mode, executing a program to save
30 the current BIOS to a file. The BIOS file may be saved into a master template,

- 34 -

backup or archive. Alternatively, the BIOS file may be modified by the repair process to change the boot sequence. If the BIOS file is updated then it must be loaded into the computer system to take effect. Effectively the boot sequence may be changed to another DSD, such as a second hard drive. The external SCSI disk with a specific
5 "id" may become the "boot device". Another option involves storing multiple copies of the BIOS file, each having a different boot sequence, uploading the appropriate BIOS file may allow booting from a particular boot device (e.g., IDE hard drive partition 1, SCSI device "id 0", USB disk, Jaz drive, etc.). An external device may be the boot device and start or continue the repair process.

10 In another embodiment, a secondary boot device may be attached as an external Data Storage Device to a computer system (e.g., connect to a parallel port). This secondary boot device may activate or manage the repair process. The secondary boot device may contain programs to conduct processes such as reformatting another data storage device (e.g., internal or external hard drive),
15 copying data from a Master Template, copying data from a backup or archive.

A program on the secondary boot device, or accessible to the secondary boot device, may be activated to create a master template, backup, or archive of and data accessible by the computer system (e.g., the user's main drive).

A program on the secondary boot device, or accessible to the secondary boot
20 device, may be activated to repair a data storage device on the computer system (e.g., the user's main drive that needs to be repaired). In this scenario, the Master Template, Backup, or archive Data Storage Device(s) may be attached externally via USB, firewire, etc. The program may actively search for Master Templates, Backups, or archive DSD(s) and present the user with a list of options for restoring the
25 computer system. Alternatively, the repair process may determine and select the best restore options and continue the repair process.

In another embodiment the repair process may be initiated by insertion of a floppy, cd, dvd, or use any other form of removable storage/memory or startup device, and rebooting the computer system. The removable storage/memory or startup
30 device may boot if the BIOS boot sequence contains a sequence in which the boot

- 35 -

order enables a removable media to act as the boot device. Booting from the removable media may trigger or activate an automated repair process (e.g., a program located on the removable media or an external device). Booting from the removable media may activate a mechanical device or program logic to initiate the repair process
5 (e.g., switch hard disk device id's and initiate a reboot sequence to boot from another device to continue the repair process).

In another embodiment, a repair program or part of the repair process may be placed in a StorExecute, microcontroller, ASIC, etc. The repair program may activate a repair process. The repair program may include managing the repair process.
10 Functions which may be performed include reformatting data storage device(s), switching between boot devices, switching electrical components within the computer system or external components, copying data to/from data storage device(s), (e.g., copying master templates, backups, etc, or any portion to another data storage device), and other repair functions. The repair process, may also be located, integrated, or
15 embedded in an external device. A switch trigger that activates the repair process may also be located, integrated, or embedded in an external device.

In one embodiment, the startup device may be selected by a StoreExecute. Alternatively, a device identity may be assigned by a StoreExecute. The necessity to perform switching through the use of jumpers is thereby reduced. For example if a
20 repair process is triggered, a StoreExecute may assign device identities to data storage devices or may decide which data storage device shall be used for the repair process, and which data storage device shall be used for boot data storage device if rebooting is utilized in the repair process.

In one embodiment during "on-the-fly" repairs, an external data storage device
25 may be utilized for such things as the Master Template or backups, or for software used for the repair process.

In this embodiment, an external data storage device ("DSD") is attached to a typical personal computer that contains an internal data storage device. The internal DSD may be referred to as the "main user" data storage device. An external DSD
30 may be attached via any available external connection.

- 36 -

Example of external data storage device (“DSD”) for repairing a computer:

In this example, a user attaches an external data storage device (“DSD”) to a computer with any available external connection (e.g., Firewire, USB, SCSI, etc.).

- 5 An external connection may include USB, USB 2, Firewire, IEEE 1394, PS/2, parallel, serial, PCMCIA, SCSI, and other protocols and method of communicating with an external device.

The user installs software on “main user” DSD that initiates a program to create a master template, and schedules Backups to execute every Friday morning.

- 10 The master template is created by the program and stored on the external data storage device. Every Friday morning the repair process runs and stores a backup of additional information to the external data storage device.

A micro-controller and EPROM may be attached to the computer to perform part of the repair process. Attachment may be via any available external connection.

- 15 The micro-controller and EPROM may be integrated into the external data storage device.

A switch trigger may be attached to the computer. Attachment may be via any available external connection. The switch trigger may be integrated into the external data storage device.

- 20 As another example, the main user data storage device is accidentally erased or damaged and that the computer system will not boot. The user decides to repair computer and initiates the repair process by activating a switch trigger, which initiates the following process:

- 25 The micro-controller may interrogate the BIOS of the computer system to determine its current boot up sequence. EPROM may store instructions for how to accomplish this.

The micro-controller may determine that it is necessary to alter the boot sequence so that the externally attached data storage device will become the boot device. The micro-controller and associated EPROM may flash the BIOS in order to

- 37 -

accomplish this. The micro-controller may then send a command to computer to reboot the computer. When the computer reboots, it will reboot from the external data storage device.

Following the boot up, programs which are located on the external data
5 storage device may execute the repair process as defined herein.

The foregoing descriptions of specific embodiments and best mode of the present invention have been presented for purposes of illustration and description. They are not intended to be exhaustive or to limit the invention to the precise forms disclosed, and obviously many modifications and variations are possible in light of
10 the above teaching. The embodiments were chosen and described in order to best explain the principles of the invention and its practical application, to thereby enable others skilled in the art to best utilize the invention and various embodiments with various modifications as are suited to the particular use contemplated. It is intended that the scope of the invention be defined by the claims appended hereto and their
15 equivalents.

Attached is a 209-page Appendix which is a part of this specification. The Appendix includes the following documents:

- 20 • "Description of Self-Repairing System" (Text, 5 pages; Drawings, 4 Pages; Code, 5 Pages)
- "Backup and/or Repair System - Multi-User System" (Text, 43 Pages)
- Diagrams (Text, 18 Pages)
- Table of Which Diagrams Go With Which Embodiments (Text, 1 Page)
- 25 • Figures, S Series (Drawings, 20 Pages)
- Figures, F Series (Drawings, 38 Pages)
- Figures, W Series (Drawings, 32 Pages)
- Figures, M Series (Drawings, 5 Pages)
- Figures, E Series (Drawings, 17 Pages)
- 30 • Figures, L Series (Drawings, 21 Pages)
